

Helping Refine an Event Planning App That Won Google Play's 2024 Best App Award

Partiful streamlines event planning with a perfect mix of fun design and practical functionality, bringing everything you need to plan an interactive event in one place.

The client was looking for experts to improve the functionality of its Android app, focusing on design, stability, and usability. We joined the project, recreating Android-specific features, helping to increase user engagement, and improving retention to drive more downloads.

In 2024, Partiful won the Google Play's Best App Award and was recognized as App of the Day by Apple.

Challenges

Partiful came to us with a clear mission: to improve and expand its Android app version.

The goal was to achieve feature parity across both iOS and Android, delivering a consistent user experience. However, this presented several challenges such as building custom transparent videos or recreating iOS-specific features like blur effects.

Recreating blur effects on Android

To ensure feature parity across platforms, we needed to recreate the blur effect on Android. What seemed like a straightforward task quickly turned into a party pooper.

Blur effects are central across the Partiful app, from modals to full-page backgrounds. Since React Native didn't natively support blur effects on Android, replicating this effect with existing tools was like trying to keep a dance floor full with no music.

We worked closely with Partiful's design team to find a solution. As the app was already using ExpoBlur, we tried using a native blur view based on the BlurView library. However, BlurView was still experimental on Android and caused numerous issues like unblurred text, white flashes, or poor performance.

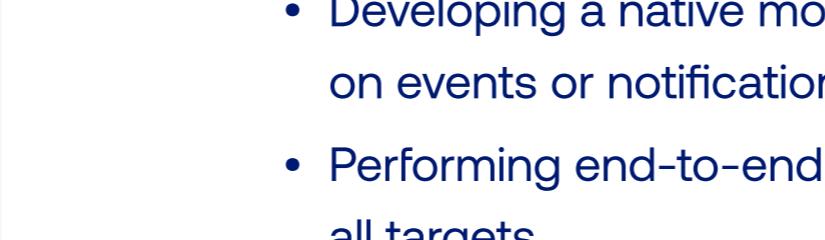

On top of that, it took screenshots of the content and applied the blur afterward, draining excessive resources.

With the tight timeline, we explored alternatives to the blur effect, considering options like solid colors, textured backgrounds, images, and various gradient types. For blurring images, we decided to use the built-in cross-platform blurRadius. Ultimately, Partiful opted for linear gradients, which were easy to implement, didn't impact performance, and offered a visually appealing, stable, and responsive solution.

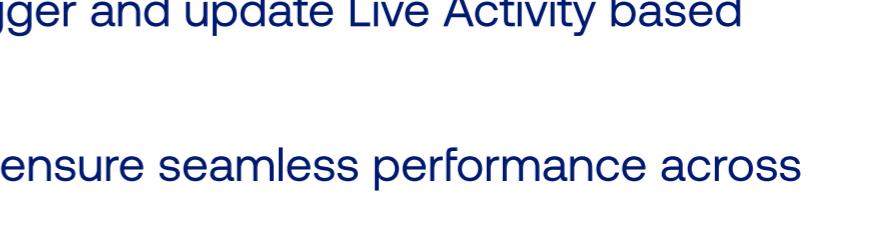

1. Examples of blur issues on buttons:

2. We replicated the effect from iOS using RadialGradient and React Native SVG:

3. We applied the same solution to the buttons, automatically blurring the background:

Bringing transparent video to Android

To give Android users the full app experience, Partiful wanted to bring over the transparent video effect from iOS. Since existing solutions didn't cover this in React Native, we helped build it natively for Android.

The first hurdle was ExpoPlayer, the video player behind react-native-video and expo-video, which doesn't support alpha-channel videos. This meant high-quality transparent videos couldn't retain their transparency. We solved this by extracting the alpha channel from RGBA videos and merging it with the color video for seamless playback.

Next, we helped tackle Android implementation. The key was a custom TextureView to overlay the video's bottom half transparently while displaying the top half normally. We used OpenGL to render the videos, but setting up the EGL context took extensive iteration to ensure everything worked without missing a beat. Once we had transparent videos rendering natively, we helped Partiful make an API to connect the native views, video player, and React Native's JavaScript code.

The cherry on top? Transparent videos run on the GPU, meaning all the heavy lifting is handled by the graphics card instead of the CPU, keeping the app fast and efficient.

Developing Live Activity on iOS

After fine-tuning the Android app to meet Partiful's expectations, the client decided to keep the momentum going and asked us to add Live Activity to the iOS app version. Live Activity is Apple's interactive notification feature that shows real-time updates like event location, date or time right in the Notifications Center and in the Dynamic Island.

Since this feature requires iOS native code in Swift and SwiftUI, we integrated it into React Native by creating custom native modules. We focused on:

- Implementing a WidgetKit extension for Live Activity
- Using SwiftUI to design the UI of Live Activity
- Developing a native module to trigger and update Live Activity based on events or notifications
- Performing end-to-end testing to ensure seamless performance across all targets

This allowed us to bridge the gap between JavaScript and iOS components, ensuring smooth real-time updates and UI synchronization.

Creating an App Clip for iOS to drive more downloads

To expand Partiful's reach and drive more downloads, we developed an App Clip to essential features. The main goal of the App Clip is to throw a mini "party" for event attendees and confirm attendance, giving them a taste of the app's value and encouraging more downloads of the full version.

As building the App Clip required creating a separate navigation stack, we replicated the navigators from the main app to maintain a seamless user flow. This way, we ensured a consistent user experience across both the App Clip and the full app version.

Context refactoring for improved app performance

We helped Partiful identify performance bottlenecks in its monolithic data structure. This single, large context caused frequent re-renders whenever components accessed shared values, slowing down the app.

To address it, we recommended refactoring the context, splitting the monolithic structure into more manageable modules. The goal was to reduce unnecessary re-renders by isolating specific data into their own contexts. With clear guidelines provided by the client team, we helped implement a modular

architecture, making the app more responsive. As a top contributor, we also supported Partiful in optimizing Expo upgrades, ensuring smooth integration across workspaces and contexts, which made the app more maintainable and scalable.
